

CAPTCHA IMPLEMENTATION IN DJANGO

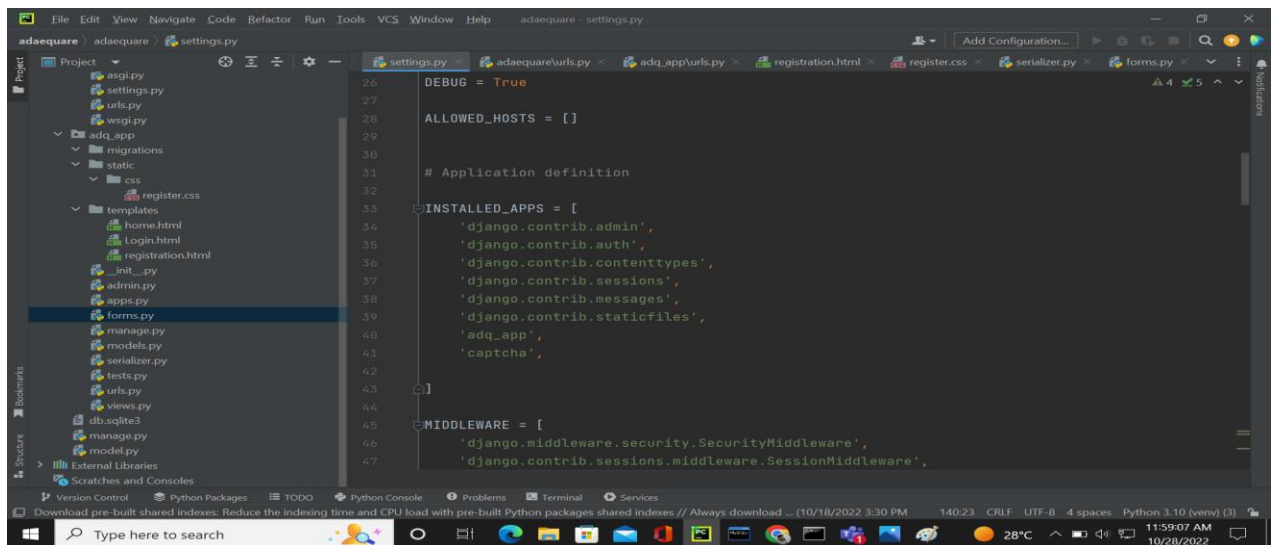

Step1:

First install simple captcha module in our Django project

--->pip install Django-simple-captcha

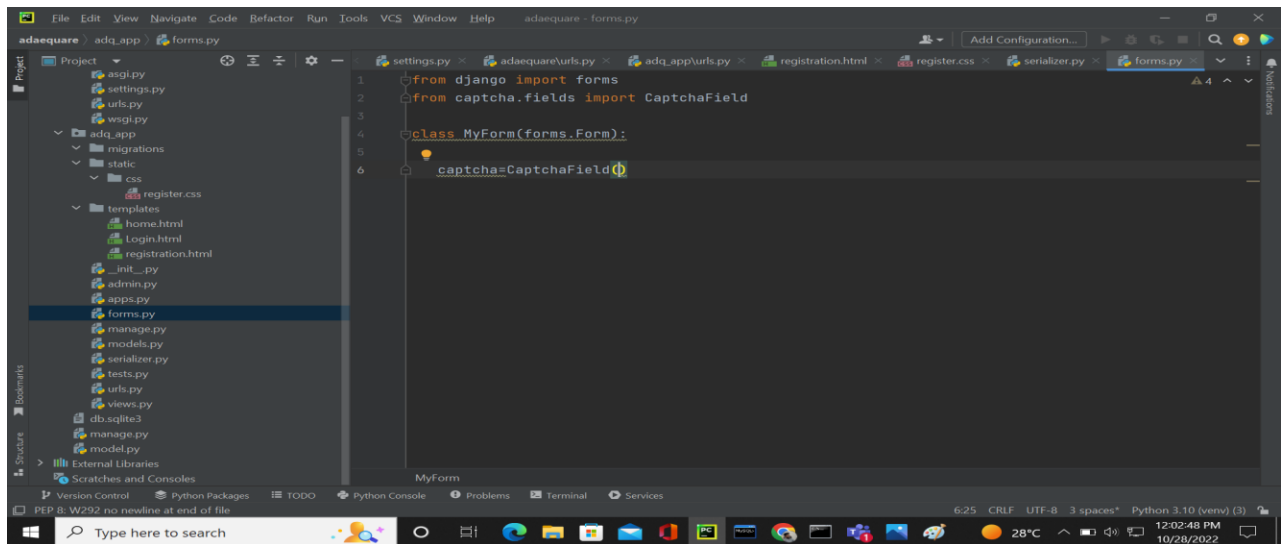

Step2:

Add captcha in django - project settings.py

Step3:

Create Captcha Field in django form.py

Step4:

Make migration:

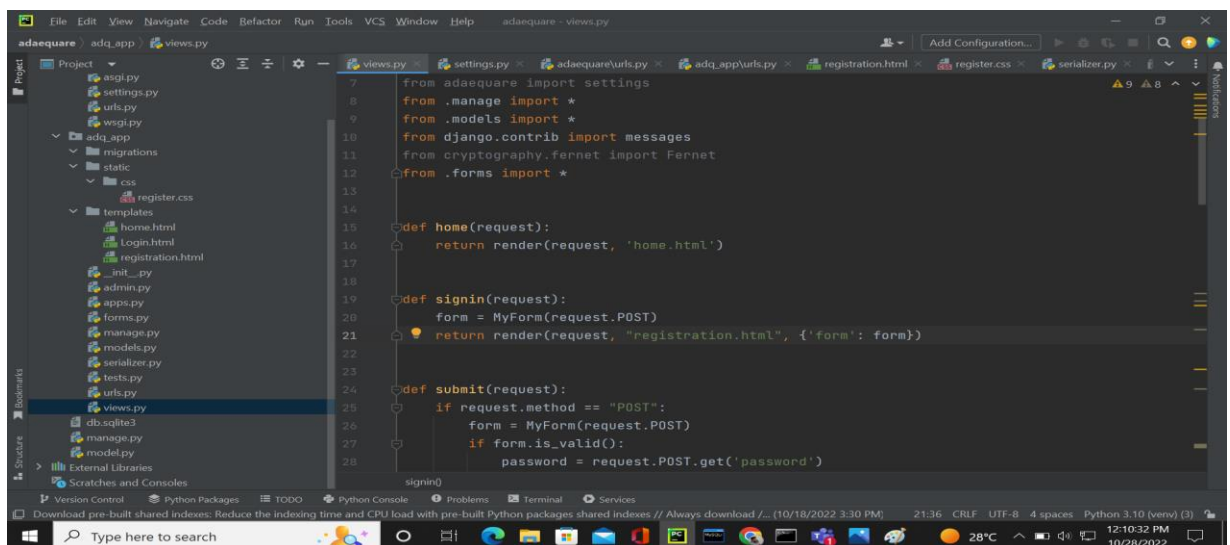

-->python manage.py make migration

Migrate:

-->python manage.py migrate

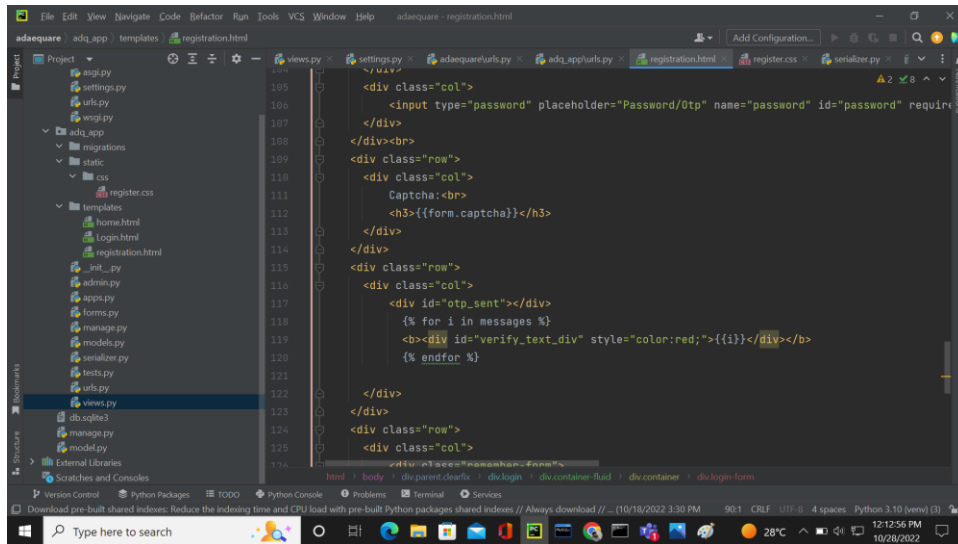

Step5:

Create a view for the captcha Form

Step6:

Retrieve backend Django form to the front end (home.html)

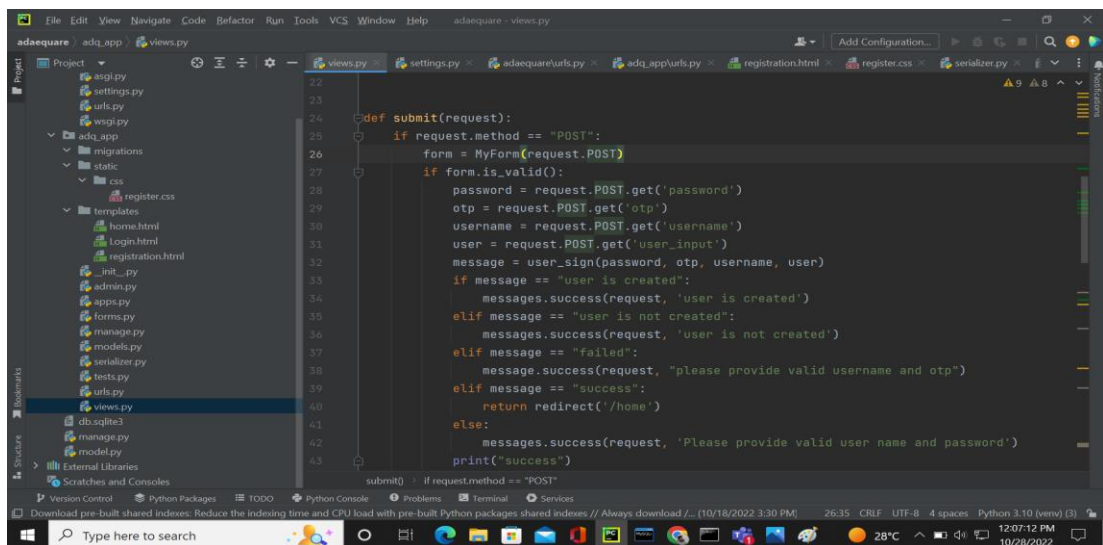

The screenshot shows the VS Code editor with the `registration.html` file open. The file contains HTML code for a registration form. The code includes a password input field, a captcha field, and a submit button. The form is styled with Bootstrap classes. The code is as follows:

```
<div class="col">
    <input type="password" placeholder="Password/Otp" name="password" id="password" required="" />
</div>
</div>
<div class="row">
    <div class="col">
        Captcha:
        <div class="col">
            <h3>{{form.captcha}}</h3>
        </div>
    </div>
</div>
<div class="row">
    <div class="col">
        <div id="otp_sent"></div>
        {% for i in messages %}
        <b><div id="verify_text_div" style="color:red;">{{i}}</div></b>
        {% endfor %}
    </div>
</div>
</div>
<div class="row">
    <div class="col">
```

Step7:

Captcha Validation:

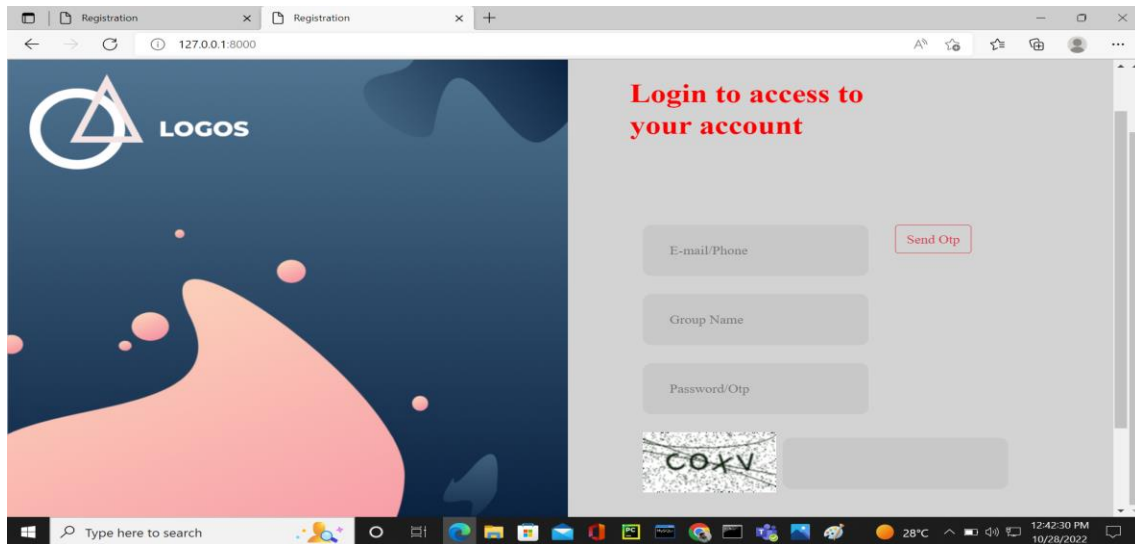

The screenshot shows the VS Code editor with the `views.py` file open. The file contains a `submit` function that handles the registration form submission. The function checks if the request method is POST, validates the form, and then checks if the user is created or not. The code is as follows:

```
def submit(request):
    if request.method == "POST":
        form = MyForm(request.POST)
        if form.is_valid():
            password = request.POST.get('password')
            otp = request.POST.get('otp')
            username = request.POST.get('username')
            user = request.POST.get('user_input')
            message = user_sign(password, otp, username, user)
            if message == "user is created":
                messages.success(request, 'user is created')
            elif message == "user is not created":
                messages.success(request, 'user is not created')
            elif message == "failed":
                messages.success(request, "please provide valid username and otp")
            elif message == "success":
                return redirect('/')
            else:
                messages.success(request, 'Please provide valid user name and password')
        print("success")
```

Result:

Page will appear like below

* If entered incorrect Captcha then it will show error message
